STRONTIUM 261

8. REGULATIONS AND ADVISORIES

The international, national, and state regulations and guidelines regarding stable strontium in air, water, and other media are summarized in Table 8-1. The regulations and guidelines regarding radioactive strontium are summarized in Tables 8-2 and 8-3.

Stable Strontium. An MRL of 2.0 mg strontium/kg/day has been derived for intermediate-duration oral exposure to strontium. The MRL is based on a NOAEL of 140 mg strontium/kg/day for skeletal toxicity in young rats (Storey 1961).

A chronic RfD of 0.6 mg/kg/day has been derived by EPA for strontium (IRIS 2001). The RfD is based on a NOAEL of 190 mg strontium/kg/day for skeletal toxicity in young rats (Storey 1961).

The EPA has not classified stable strontium for human carcinogenicity (IRIS 2001). A number of agencies have classified strontium chromate as a human carcinogen by the inhalation route, on the basis of occupational and animal studies. The carcinogenicity of strontium chromate is attributed to the hexavalent chromium ion and not to strontium. The American Conference of Governmental Industrial Hygienists (ACGIH) has given strontium chromate the classification A2, suspected human carcinogen, and has established an 8-hour time-weighted-average (TWA) of 0.0005 mg/m³ for occupational exposure (ACGIH 2000). The International Agency for Research on Cancer (IARC) has assigned strontium chromate, along with other chromates, to Group 1, as a human carcinogen (IARC 1998a). No other stable strontium compound is listed by IARC.

Radioactive Strontium. No MRLs were derived for inhalation or oral exposures to radioactive strontium. The EPA has not derived an RfC or RfD for radioactive strontium (IRIS 2001). The EPA has determined that all radionuclides, including radioactive strontium, are known human carcinogens, and has assigned them to Group A (EPA 1997b). The EPA (1997b) has calculated carcinogenicity slope factors for radioactive strontium isotopes (Table 8-2). The IARC has determined that all internally deposited beta emitters, including radioactive strontium, are carcinogenic to humans and has assigned them to Group 1 (IARC 2000).

Because of the potential for ionizing radiation to cause deterministic (acute radiation syndrome) and nondeterministic (cancer) health effects in exposed individuals, safe dose guidelines and regulations have been established for radionuclides in air and water by a number of international and national agencies

(Tables 8-2 and 8-3). Regulations and guidelines that protect against deterministic effects are based on identified acute thresholds doses for those effects, with a reduction to protect sensitive populations and provide safety margins to account for uncertainties. Those that protect against nondeterministic effects use the observed frequencies with which those effects occur at high doses, account for uncertainties that may exist, and assume a linear dose-effect relationship to calculate the doses at which the effects would be presumed to occur at some acceptable frequency, such as the range of 10⁻⁴ to 10⁻⁶, which EPA often considers. This proportionality assumes a linear no threshold (LNT) dose effect curve. During the last decade, there have been reductions in LNT-based public radiation dose limits and site cleanup levels that have increased the scope and cost of medical, occupational, and environmental radiation protection efforts. Some recent studies found a reduction in health effects when the dose was delivered at lower dose rates, indicating a potential application to future protection guidelines and regulations.

The International Commission on Radiological Protection (ICRP) provides guidance on the fundamental principles regarding the biological effects of exposure to ionizing radiation and recommends exposure limits based on these analyses. In the United States, the National Council on Radiation Protection and Measurements (NCRP) was chartered in 1964 by the U.S. Congress to: (1) disseminate information of public interest and recommend radiation levels to protect the public, (2) support cooperation among organizations concerned with radiation protection, (3) develop basic concepts about radiation protection, and (4) cooperate with the ICRP and the International Commission on Radiation Units and Measurements. Even though the NCRP is a nongovernmental organization, it provides recommendations that guide the establishment of federal radiation policies, agency requirements, and statutory laws. Through the governmental agencies that rely on NCRP recommendations, the work of this organization has a significant impact on the many activities in the United States involving the use of radiation and radioactive materials.

The EPA sets radiation safety policy and basic safety standards. The execution of this policy is assigned to the various regulatory agencies, including the EPA itself, for application to the specific activities that they regulate. The U.S. Nuclear Regulatory Commission (USNRC), an independent government agency, regulates commercial nuclear power reactors; research/test/training reactors; fuel cycle facilities; and the transport, storage, and disposal of nuclear materials and waste (USNRC 1997b). The EPA is responsible for protecting the public and the environment and for cleanup of radioactively contaminated sites (EPA 1997a).

The Food and Drug Administration (FDA) develops standards for radioactive material concentrations in food (FDA 1998), and medical devices used in radiation therapy (FDA 1997). The FDA recently updated its guidance document that presents recommended action levels for radionuclides in foods, both domestic and imported (FDA 1998). These derived intervention levels (DILs) are estimated levels in food that could lead to individuals receiving a radiation equivalent dose equal to the FDA protection action guide (PAG) that is set as the more limiting of either 0.5 rem (5 mSv) for committed effective dose or 5 rem (50 mSv) committed dose equivalent to any individual tissue or organ. Table 8-2 presents the most restrictive DILs for strontium.

Transport of radioactive materials is regulated by the Department of Transportation (DOT) in conjunction with the USNRC. Coordinating government emergency response to accidents involving radioactive materials is the responsibility of the Federal Emergency Management Administration (FEMA).

National regulations governing the occupational exposure to ionizing radiation include USNRC regulations (10 CFR 20), the Occupational Safety and Health Administration (OSHA) standards for ionizing radiation (29 CFR 1910.1096), and the Department of Energy (DOE) standards for occupational radiation protection (10 CFR 835). National regulations concerning general population exposure to radiation have been developed by the EPA and USNRC based on the dose limit recommendations of the ICRP (ICRP 1997) and the NCRP (NCRP 1993).

Currently there are 29 "NRC Agreement States." An agreement state is any state that has entered into an agreement with the USNRC under Section 274 of the Atomic Energy Act of 1954, as amended. The USNRC relinquishes to these states the majority of its regulatory authority over source, by-product, and special nuclear material in quantities not sufficient to form a critical mass. However, the regulation of nuclear reactors is under USNRC jurisdiction. In the remaining states, USNRC still handles all of the inspection, enforcement, and licensing responsibilities.

The basic philosophy of radiation safety is to minimize unnecessary radiation exposure. The specific objectives of radiation safety guidance as stated by NCRP are (1) to prevent the occurrence of severe radiation-induced deterministic (nonstochastic) disease, and (2) to limit the risk of the nondeterministic (stochastic) effects (fatal cancer, and genetic effects) to a reasonable level compared with nonradiation risks and in relation to societal needs, benefits gained, and economic factors. In addition to regulations that set upper limits on radiation dose, the concept of ALARA (As Low As Reasonably Achievable) was introduced to ensure that workplace endeavors resulting in exposures to radiation provide sufficient

STRONTIUM 8. REGULATIONS AND ADVISORIES

benefits that offset any potential detriment they cause (ACGIH 2000). The goal is not to eliminate all radiation exposure, which would not be possible, but instead to strive for an appropriate balance between protection of public health and reasonable costs (economic, social, etc.) while maintaining desirable dose limits. The ACGIH has adopted the occupational exposure guidance of the ICRP (ACGIH 2000).

^aThe limits apply to the sum of the relevant doses from external exposure in the specified period and the 50-year committed dose (to age 70 years for children) from intakes in the same period.

Column 1: The sum of the fractions rule for mixtures of radionuclides. For determining classification for waste that contains a mixture of radionuclides, it is necessary to determine the sum of fractions by dividing each nuclide's concentration by the appropriate limit and adding the resulting values. The appropriate limits must all be taken from the same column of the same table. The sum of the fractions for the column must be less than 1.0 if the waste class is to be determined by the column. Example: A waste contains ⁹⁰Sr in a concentration of 50 Ci/m³ and ¹³⁷Cs of 22 Ci/m³. Since the concentrations both exceed the values in Column 1, Table 2, they must be compared to Column 2 values. For ⁹⁰Sr fraction 50/150=0.33; for ¹³⁷Cs fraction, 22/44=0.5; the sum of the fractions=0.83. Since the sum is less than 1.0, the waste is Class B.

^mGroup A: human carcinogen

ⁿDerived intervention levels (DIL) are concentrations of radioactivity in food whose consumption would deliver a committed effective dose equivalent equal to the most limiting of the protection action guides (PAGs) developed by FDA (1998).

°Radioactive slope factors calculated by EPA's Office of Radiation and Indoor Air (ORIA). Slope factors are central estimates in a linear model of the age-averaged, lifetime attributable radiation cancer incidence (fatal and nonfatal cancer) risk per unit of activity ingested, expressed as risk per picocurie (pCi).

PInhalation slope factors are central estimates in a linear model of the age-average, lifetime attributable radiation cancer incidence (fatal and nonfatal cancer) risk per unit of activity inhaled, expressed as risk per picocurie (pCi).

External slope factors are central estimates of the lifetime attributable radiation cancer incidence risk for each year of exposure to external radiation from photon-emitting radionuclides distributed uniformly in a thick layer of soil, expressed as risk/year per pCu per gram of soil.

Sum of external and internal exposures but excluding doses from natural sources.

ACGIH = American Conference of Governmental Industrial Hygienists; ADEC = Alaska Department of Environmental Conservation; ALI = annual limits on intake; BNA = Bureau of National Affairs; CFR = Code of Federal Regulations; DAC = derived air concentration; DEP = Department of Environmental Protection; DOE = Department of Energy; DOT = Department of Transportation; EPA = Environmental Protection Agency; FDA = Food and Drug Administration; HSDB = Hazardous Substances Data Bank; I = insoluble; IARC = International Agency for Research on Cancer; ICRP = International Commission on Radiological Protection; MCL = maximum contaminant level; MCLG = maximum contaminant level goal; MDEQ = Michigan Department of Environmental Quality; mSv = millisievert; MTHM = metric tons of heavy metal; NCRP = National Council on Radiation Protection; NIOSH = National Institute for Occupational Safety and Health; NRC = Nuclear Regulatory Commission; OSHA = Occupational Safety and Health Administration; PAG = protective action guide; REL = recommended exposure limit; S = soluble; TWA = time-weighted average

^bWith the further provision that the effective dose should not exceed 50 mSv in any single year. Additional restrictions apply to the occupational exposure of pregnant women.

^cThe limitation on the effective dose provides sufficient protection for the skin against stochastic effects. An additional limit is needed for localized exposures in order to prevent deterministic effects.

^dGroup 1: human carcinogen

^eIn special circumstances, a higher value of effective dose could be allowed in a single year, provided that the average over 5 years does not exceed 1 mSv per year.

^fClass D: all soluble compounds except SrTiO

⁹Class Y: all insoluble compounds and SrTiO

^hClass D: refers to materials with retention times in the pulmonary region of <10 days

Class W: refers to materials with retention times in the pulmonary region of 10–100 days

^jClass Y: refers to materials with retention times in the pulmonary region of >100 days

^kRelease limit per 1,000 metric tons of heavy metal (MTHM) or other unit of waste

^aICRP (1994)

ALI = Annual Limits on Intake; AMAD = Activity Median Average Diameters; Bq = Bequerels; Ci = Curies; d = day; hr = hour; yr = year

^b For internal exposures, ICRP (1994) recommends an effective dose limit of 100 mSv over 5 years (averaging 20 mSv per year). The Annual Limits on Intake (ALI in Bequerels) were calculated by dividing the annual effective dose limit (0.02 Sv) by the dose coefficient (e(50)) in Sieverts/Bequerel.

class (1994) calculated inhalation dose coefficients for particles with AMAD of 1 or 5 µm.

^dFractional absorption factor used by ICRP (1994: Annexes E and F) to calculate effective dose coefficients. A value of 0.3 was used for unspecified strontium compounds and 0.01 was used for strontium titanate.
